Abstract: Rapeseed is major oilseed crop of Nepal but its yield is limited due to various factors and one of the major limiting factors is leaf blight disease caused by *Alternaria brassicae* (Berk.). An experiment was conducted at Oilseed research Program, Nawalpur, Sarlahi, Nepal during two consecutive years viz. 2019 and 2020 to screen the rapeseed genotypes against alternaria leaf blight disease. The research was conducted in augments design with each genotype sown in two rows of 3 m length 30 cm apart and disease was allowed to develop naturally in the field. Four times scoring of disease was done starting from 49 days after sowing at seven days interval. Out of one hundred and ninety genotypes used in evaluation, there were no genotypes that were immune or completely resistant to the disease but thirty one genotypes during 2019 and eight genotypes during 2020 were found to be moderately resistant to the disease. One genotype ICT 2010-7 was found to be moderately susceptible in both the years' observations. Area under disease progress curve (AUDPC) value for three genotypes (ICT 2001-6, ICT 2001-7, and ICT 2010-9) during 2019 and six genotypes (ICT 2010-7, S R O 2, ICT 2004-1, NGRC 2798, ICT 2004-42, and ICT 2006-3) during 2020 was lower (<400) representing lower disease progress. Hence the genotypes that were moderately resistant as well as have lower AUDPC value can be utilized in future by plant breeders and plant pathologist for development of tolerant varieties as durable resource for disease management.

Keywords: Alternaria leaf blight, Genotypes, Rapeseed, Resistant, Nawalpur

Introduction

Rapeseed (*Brassica campestris* L. var. Toria, 2n=20)) and mustard (*Brassica juncea L*. Czern and Coss, 2n=4x=36) are major oilseed crops in contributing nearly 84% of total oilseed produced in Nepal (MoALD, 2021). Rapeseed and mustard oil has multiple daily uses in Nepalese family. The national production merely meets 68.7% of national requirements and huge amount of rapeseed (106599 ton) is being imported (NFTS, 2020). Although high volume of rapeseed is imported the national production could not be increased satisfactorily as there are various biotic and abiotic factors that limit rapeseed production.

Among the various factors, biotic factor leaf blight disease caused by *Alternaria brassicae* (Berk.) is the most responsible factor reporting about 32-57 percent yield losses in rapeseed in Nepal. Apart from yield the disease also reduced the produce quality by reducing seed size, oil content and impairing seed colors (Kaushik et al., 1984). Various conventional (fungicides and fertilizers application, soil dressing, seed treatments, tillage operations etc. and non-conventional (plant activators, bio-control agents, plant extracts, ionic contents comparisons through biochemical analysis etc. approaches are being utilized used for alternaria leaf spot disease management (Bhatt et al., 2009).

In chemical control measures there is need of repeated application of fungicides resulting difficulty in spraying in standing crop and sometimes being un-economical practice, so there is need of alternate approach for disease management (Chattopadhyay et al., 2005). Fungicide applied for disease control is contaminating not only soil and environment but also degrading the quality of oil at the same time so there is need of adequate, eco friendly and promising approach for quality production (Singh et al., 2015). https://dx.doi.org/10.29322/IJSRP.14.01.2024.p14515

among the farmers on the risk involved in the use of fungicides much attention is being focused on the integrated approach pathogen management (Kumar et al., 2014) and the method of controlling the disease by using resistant varieties is to be recognized through study on resistant source (Shah et al., 2005; Prasad et al., 2003). Host plant resistance is very important approach to control much disease of various crops in many developing countries (Tengey et al., 2018). Alternaria blight severity on rapeseed-mustard differs among seasons and regions and also between individual crops within a region. This may be due to existence of variability within the isolates of *Alternaria* spp. (Meena et al., 2005; Verma et al., 2006). So identification of resistant source could be an appropriate means for addressing the problem. Sometimes plant morphology and anatomy is also related to govern the resistance of crop and protect plants from pathogen invasion (Barsa et al., 1985, Kaur and Dhillon, 1990).

Therefore, the field experiments were designed and conducted at Oilseed Research Program (ORP), Nawalpur, Sarlahi during 2019 and 2020 to find the resistant genotypes which can be included in the breeding program and develop resistant cultivars.

Material and Methods

Experimental Site

The field experiment was conducted at field of ORP, Nawalpur, Sarlahi, Nepal in 2019 and 2020. The collection of indigenous and exotic rapeseed genotypes at ORP was used for the experiment.

Experimental Materials, Design and Setup

A total of one hundred ninety genotypes of rapeseed received from national as well as international institution including check were evaluated against alternaria leaf spot during 2019 and 2020 respectively. Trial was conducted during winter season under natural epiphytotic condition in augmented design in a single replication with single genotype sown in 2-rows of 1m 3m length having spacing line to line 30 cm and plant to continuous. The nursery was surrounded by 2-rows of susceptible border mixture to produce sufficient inoculums to infect the test entries. Chemical fertilizer was applied @ 60:40: 20; N: P₂O₅: K₂O kg/ha in which phosphatic and potassium fertilizer used as a basal dose while nitrogenous fertilizer in a split dose. All the agronomic practices were provided for excellent growth of the crop and disease development.

Disease Assessment

Alternaria blight disease scoring was done four times in 7 days interval on (0-9) scale suggested by Ghosh et al. 2009, after completion of flowering of the crop (49 days after sowing) and maximum score was considered for the evaluation of test entries. For visual estimation of severity, 0-9 point scale (No infection – 0; 0-10% leaf area infected – 1; 10-20% leaf area infected – 2; 20-30% leaf area infected – 3; 30-40% leaf area infected – 4; 40-50% leaf area infected – 5; 50-60% leaf area infected – 6; 60-70% leaf area infected – 7; 70-80% leaf area infected – 8; 80-90% or more leaf area infected – 9) were used for rating of all foliar diseases studied. Similarly, area under disease progress curve (AUDPC) was calculated and total AUDPC value was considered for evaluation.

Results and Discussion

Meteorological Information

Weather data on average minimum temperature, average maximum temperature and relative humidity during crop period of year 2019 and year 2020 at ORP, Nawalpur, Sarlahi were found to be favorable for disease development (Table 1). In February, the weather became congenial to disease development. Severity of alternaria blight on leaves (Meena et al., 2002) and pods (Sandhu et al., 1985) were higher in late sown crops. The coincidence of the vulnerable growth stage of plants with favorable (maximum temperature: $18-26^{\circ}C$; minimum temperature: $8-12^{\circ}C$) and humid (mean RH > 70%) results in disease severity. Most of the genotypes found susceptible to alternaria blight because of conducive weather condition during the crop season and none of the genotypes were found completely resistant to alternaria blight disease (Singh et al., 2022; Chakrabarty et al., 2018).

Disease Severity

During 2019, out of 190 genotypes were screened, none of the genotypes were found resistant or disease free; 21 genotypes were found moderately resistant (3 score in 0-9 scoring scale); 128 genotypes were moderately susceptible (4 or 5 score in 0-9 scoring scale) and 41 genotypes were found to be susceptible (6 or 7 score in 0-9 scoring scale) against alternaria blight disease (Figure 1 and Table 2). Based on total AUDPC value ICT 2004-1 was found to be mostly disease affected genotype with AUDPC value 1322 whereas the lowest AUDPC value 272 was calculated in genotype ICT 2006-6 followed by genotypes ICT 2001-7 and ICT 2010-9 with AUDPC value 350 (Table 3).

During 2020, out of 190 genotypes were screened, none of the genotypes were found resistant or disease free; 8 genotypes (viz. SRO 2, ICT 2004-1, ICT 2010-7, NGRC 2798, ICT 2004-42, ICT 2006-3, Morang-2, and ICT 2003-10) were found moderately resistant (3 score in 0-9 scoring scale); 104 genotypes were moderately susceptible (4 or 5 score in 0-9 scoring scale) and 68 genotypes were found to be susceptible (6 or 7 score in 0-9 scoring scale) and 10 genotypes were found to be highly susceptible (8 or 9 score in 0-9 scoring scale) against alternaria blight disease (Figure 1 and Table 2). Based on total AUDPC value ICT 2004-44, ICT 2001-13, ICT 2002-11 and ICT 2012-81 were found to be mostly disease affected genotype with AUDPC value 933 whereas the lowest AUDPC value 311 was calculated in genotype SRO 2 and ICT 2004-1 followed by genotypes ICT 2010-7and NGRC 2798 with AUDPC value 350 (Table 3).

During both years observation, none of the evaluated genotypes were found to be totally resistant to disease. Similar observation was made by Srivastva et al., (2001) when fifty-four lines/varieties were tested in an alternaria sick plot and none of the varieties were found to be resistant to alternaria blight. None of the variety was found disease free when 81 Indian mustard lines were screened in Faizabad, India Singh et al., (2009). The genotype ICT 2010-7 was found to be moderately resistant in both years observations whereas genotypes NGRC 2752, ICT 2012-98, ICT 2012-82, ICT 2012-61, ICT 2012-6, ICT 2012-59, ICT 2012-58, ICT 2012-27, ICT 2010-9, ICT 2010-7, ICT 2009-2, ICT 2006-4, ICT 2002-9, ICT 2001-7, ICT 2001-6, ICT 2001-44, ICT 2001-40, ICT 2001-11, NGRC 2798, ICT 2003-10, SRO 2, ICT 2006-3, ICT 2004-42 and ICT 2004-1 were found moderately resistant to alternaria blight either in 2019 or in 2020 observations (Table 2). When AUDPC value was observed the genotypes ICT 2010-7, S R O 2, ICT 2004-42, and ICT 2004-42, and ICT 2004-4, NGRC 2798, ICT 2010-7, S R O 2, ICT 2006-3 have lower AUDPC value (AUDPC < 400) during 2020 observations (Table 3). The moderately resistant varieties could be utilized for development disease tolerant varieties in future by breeder and pathologist.

Conclusions

The low productivity of rapeseed in Nepal may be due to various biotic as well as abiotic factors and alternaria blight is one of the factors responsible for reducing rapeseed yield. Use of resistance or tolerant variety is ideal and environmental approach in disease This publication is licensed under Creative Commons Attribution CC BY.

International Journal of Scientific and Research Publications, Volume 14, Issue 1, January 2024 ISSN 2250-3153

management. The moderately resistant genotypes identified will help pathologist as well as breeder to incorporate them in future crop improvement program towards breeding for alternaria bight tolerant lines in rapeseed.

Acknowledgments

We would like to thank Santosh Sah, Bishnu Bahadur Kingring, Sangita Neupane and all staffs from Oilseed Research Program for active participation and support during implementation and data recording of this research study. We would also like to thanks to National Plant Pathology Research center, Khumaltar, Lalitpur for technical assistance and Nepal Agricultural Research council (NARC) for financial support for this study.

Authors' Contributions

S. Subedi and BP Yadav designed this research and revised the article for publication. P. Wagle conducted the trial and recorded data. P. Wagle, S. Rasaily, A. Mishra and A. Chaudhary wrote the final manuscript.

Conflict of Interest

The authors declare no conflicts of interest.
